# fn make\_clamp

### Sílvia Casacuberta

This proof resides in "contrib" because it has not completed the vetting process.

Proves soundness of fn make\_clamp in mod.rs at commit 0db9c6036 (outdated<sup>1</sup>).

## 1 Hoare Triple

#### Precondition

To ensure the correctness of the output, we require the following preconditions:

- Type TA must have trait ProductOrd.
- Type M must have trait DatasetMetric.

### Pseudocode

```
def make_clamp(
      input_domain: VectorDomain[AtomDomain[TA]],
^{2}
      input_metric: M,
3
4
      bounds: (TA, TA)
5):
6
      input_domain.element_domain.assert_non_null()
7
      # clone to make it explicit that we are not mutating the input domain
8
      output_row_domain = input_domain.element_domain.clone()
9
      output_row_domain.bounds = Bounds.new_closed(bounds)
10
11
      def clamper(value: TA) -> TA:
12
          return value.total_clamp(bounds[0], bounds[1])
13
14
      return make_row_by_row_fallible(
15
16
          input_domain,
          input_metric,
17
          output_row_domain,
18
19
          clamper
20
```

#### Postconditions

Theorem 1.1. For every setting of the input parameters (input\_domain, input\_metric, bounds) to make\_clamp such that the given preconditions hold, make\_clamp raises an exception (at compile time or run time) or returns a valid transformation. A valid transformation has the following properties:

- 1. (Appropriate output domain). For every element x in input\_domain, function(x) is in output\_domain or raises a data-independent runtime exception.
- 2. (Stability guarantee). For every pair of elements x, x' in input\_domain and for every pair (d\_in,d\_out), where d\_in has the associated type for input\_metric and d\_out has the associated type for output\_metric, if x, x' are d\_in-close under input\_metric, stability\_map(d\_in) does not raise an exception, and stability\_map(d\_in) ≤ d\_out, then function(x), function(x') are d\_out-close under output\_metric.

### 2 Proof

Lemma 2.1. The invocation of make\_row\_by\_row\_fallible (line 15) satisfies its preconditions.

*Proof.* The preconditions of make\_clamp and pseudocode definition (line 5) ensure that the type preconditions of make\_row\_by\_row\_fallible are satisfied. The remaining preconditions of make\_row\_by\_row\_fallible are:

- row\_function has no side-effects.
- If the input to row\_function is a member of input\_domain's row domain, then the output is a member of output\_row\_domain.

The first precondition is satisfied by the definition of clamper (line 12) in the pseudocode.

For the second precondition, assume the input is a member of input\_domain's row domain. Therefore, by 6, the input is non-null. In addition, since Bounds.new\_closed did not raise an exception, then by the definition of Bounds.new\_closed, the bounds are non-null. Thus, by the definition of ProductOrd, the preconditions of total\_clamp are satisfied, so the output is within the bounds. Therefore, the output is a member of output\_row\_domain.

We now prove the postcondition of make\_clamp.

*Proof.* By 2, the preconditions of make\_row\_by\_row\_fallible are satisfied. Thus, by the definition of make\_row\_by\_row\_fallible, the output is a valid transformation.
